Phishing Awareness Campaign Report

Introduction:

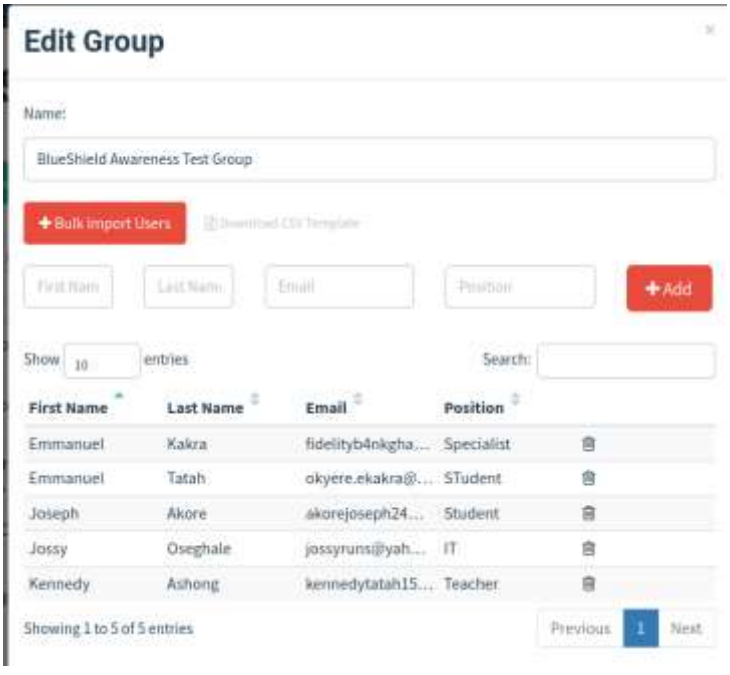

This lab exercise focused on designing and launching a controlled phishing-awareness campaign using GoPhish. The purpose was to test defensive skills in a safe environment and measure how users respond to simulated phishing attempts.

Lab Scope:

The campaign was conducted only within the lab, using fake student accounts and approved infrastructure. No real credentials or external systems were involved, ensuring the exercise remained ethical and educational.

Campaign Setup

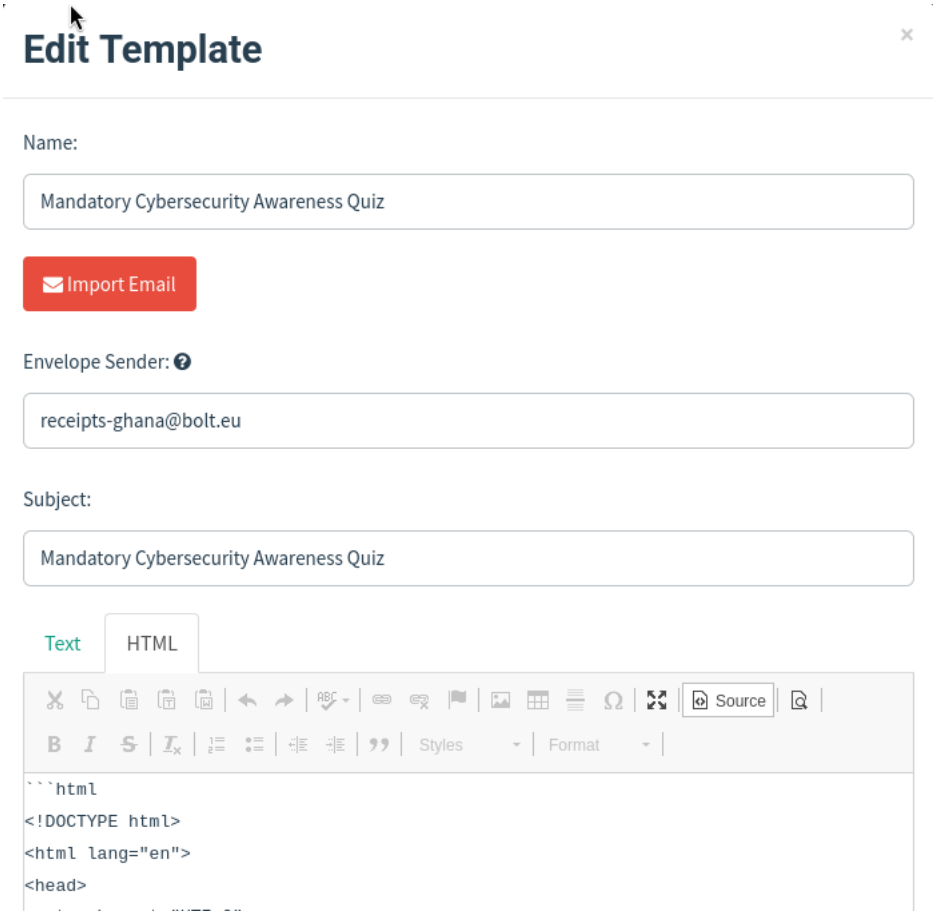

A target group of test student accounts was created. The campaign included a safe email template, a controlled landing page, and tracking variables to measure user and group actions such as email opens and link clicks.

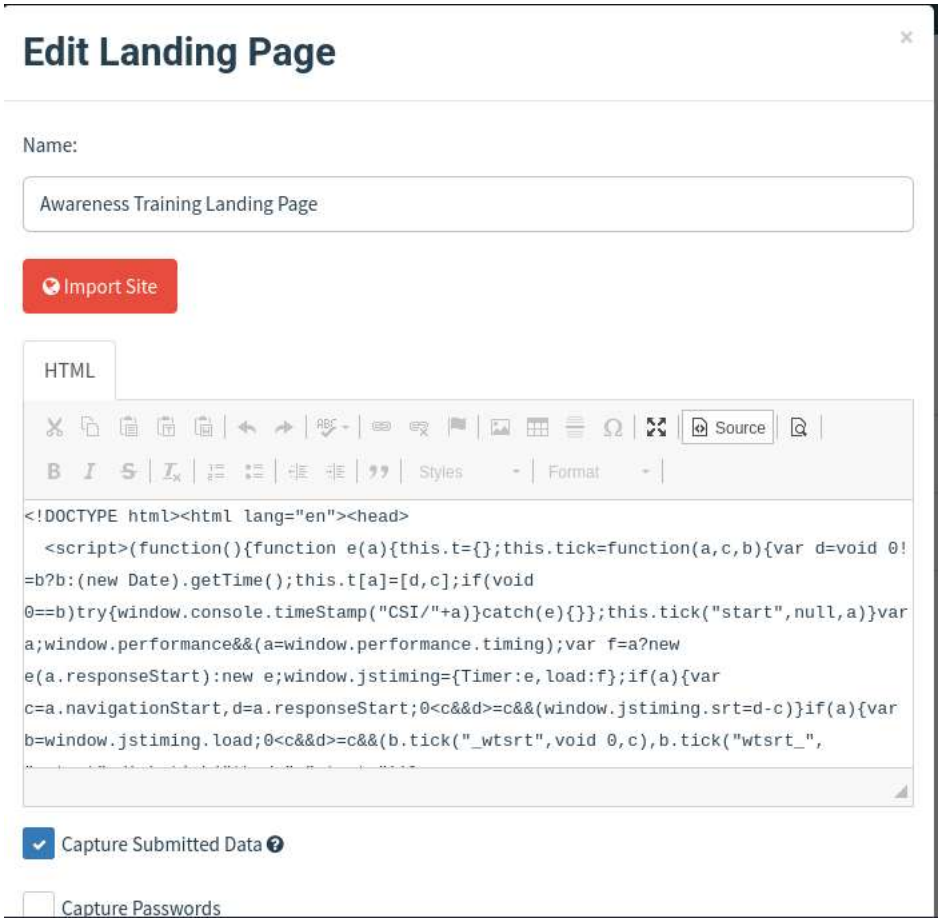

Email Template Used

The email was designed to look realistic but harmless. It included a training message and tracking links to measure engagement without collecting sensitive data.

Landing Page Used

The landing page reinforced awareness by showing an educational message. It did not request or store any real credentials but instead explained the risks of phishing and how to spot suspicious emails.

Results and Metrics

The campaign tracked key indicators such as how many emails were opened, how many links were clicked, and how many users submitted training responses. These metrics provided insight into user awareness levels.

Analysis of User Behavior

Results showed that while some users opened the emails and clicked links, others recognized the simulation and avoided interacting. This highlights varying levels of awareness and the need for continued training.

Defensive Recommendations

To reduce phishing risk, the organization should:

- Provide regular recognition and reinforcement for employees who spot phishing attempts.
- Improve communication and clarity around security policies.
- Establish consistent feedback loops so employees learn from mistakes and successes.
- Offer ongoing training to strengthen skills and build confidence in identifying phishing threats.

Conclusion:

The controlled campaign demonstrated both strengths and gaps in user awareness. By improving recognition, communication, and feedback, and by reinforcing training, the organization can foster a stronger culture of security and reduce the risk of phishing attacks.
